# Table of Contents

## 1. Concepts

- 1.1 Main Idea
- 1.2 Classical Control vs MPC
- 1.3 Mathematical Formulation

# Main Idea

## Objective:

- Minimize lap time

## Constraints:

- Avoid other cars
- Stay on road
- Don't skid
- Limited acceleration

## Intuitive approach:

- Look forward and plan path based on
  - Road conditions
  - Upcoming corners
  - Abilities of car
  - etc...

# Optimization-Based Control

Minimize (lap time)  
while avoid other cars  
stay on road  
...

- Solve **optimization problem** to compute minimum-time path

# Optimization-Based Control

Minimize (lap time)  
while avoid other cars  
stay on road  
...

- Solve **optimization problem** to compute minimum-time path
- What to do if something unexpected happens?
  - We didn't see a car around the corner!
  - Must introduce *feedback*

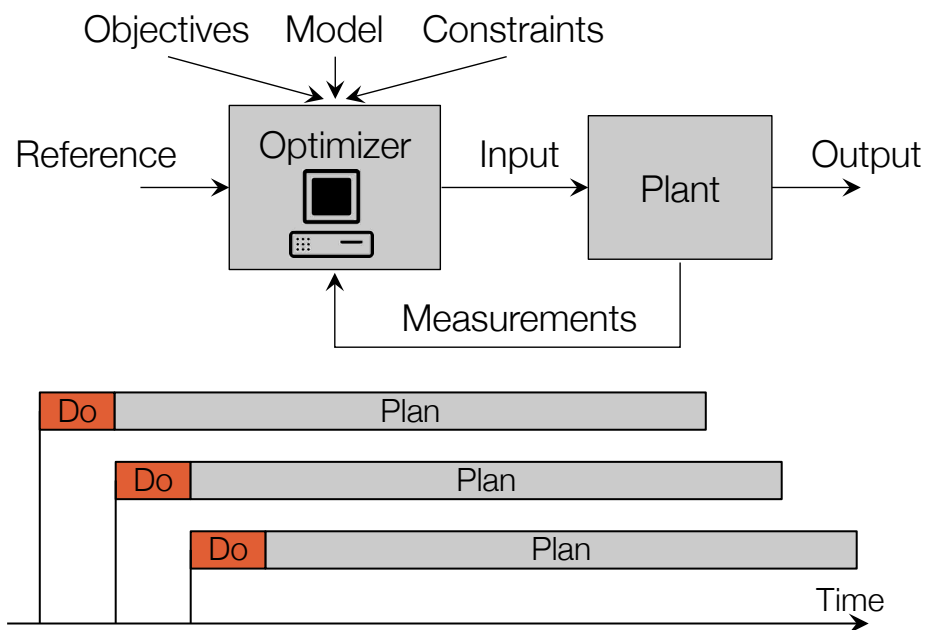

# Optimization-Based Control

Minimize (lap time)  
while avoid other cars  
stay on road  
...

- Solve **optimization problem** to compute minimum-time path
- Obtain series of planned control actions
- Apply *first* control action
- Repeat the planning procedure

# Model Predictive Control

Receding horizon strategy introduces **feedback**.

## Table of Contents

### 1. Concepts

#### 1.1 Main Idea

#### 1.2 Classical Control vs MPC

#### 1.3 Mathematical Formulation

## Two Different Perspectives

**Classical design:** design C

Dominant issues addressed

- Disturbance rejection ( $d \rightarrow y$ )
- Noise insensitivity ( $n \rightarrow y$ )
- Model uncertainty

(usually in *frequency domain*)

**MPC:** real-time, repeated optimization to choose  $u(t)$

Dominant issues addressed

- Control constraints (limits)
  - Process constraints (safety)
- (usually in *time domain*)

## Constraints in Control

All physical systems have **constraints**:

- Physical constraints, e.g. actuator limits
- Performance constraints, e.g. overshoot
- Safety constraints, e.g. temperature/pressure limits

*Optimal operating points are often near constraints.*

Classical control methods:

- Ad hoc constraint management
- Set point sufficiently far from constraints
- Suboptimal plant operation

**Predictive control:**

- Constraints included in the design
- Set point optimal
- Optimal plant operation

# Table of Contents

## 1. Concepts

### 1.1 Main Idea

### 1.2 Classical Control vs MPC

### 1.3 Mathematical Formulation

## MPC: Mathematical Formulation

$$\begin{aligned}
 U_t^*(x(t)) &:= \underset{U_t}{\operatorname{argmin}} \sum_{k=0}^{N-1} q(x_{t+k}, u_{t+k}) \\
 \text{subj. to } &x_t = x(t) && \text{measurement} \\
 &x_{t+k+1} = Ax_{t+k} + Bu_{t+k} && \text{system model} \\
 &x_{t+k} \in \mathcal{X} && \text{state constraints} \\
 &u_{t+k} \in \mathcal{U} && \text{input constraints} \\
 &U_t = \{u_t, u_{t+1}, \dots, u_{t+N-1}\} && \text{optimization variables}
 \end{aligned}$$

Problem is defined by

- **Objective** that is minimized,  
e.g., distance from origin, sum of squared/absolute errors, economic,...
- Internal **system model** to predict system behavior  
e.g., linear, nonlinear, single-/multi-variable, ...
- **Constraints** that have to be satisfied  
e.g., on inputs, outputs, states, linear, quadratic,...

# MPC: Mathematical Formulation

At each sample time:

- Measure / estimate current state  $x(t)$
- Find the optimal input sequence for the entire planning window  $N$ :  
 $U_t^* = \{u_t^*, u_{t+1}^*, \dots, u_{t+N-1}^*\}$
- Implement only the *first* control action  $u_t^*$

## Ball on Plate

- **Movable plate** (0.66m × 0.66m)
- Can be revolved around two axis  $[+17^\circ; -17^\circ]$  by two DC motors
- Angle is measured by potentiometers
- Position of the ball is measured by a camera
- *Model*: Linearized dynamics, 4 states, 1 input per axis
- *Input constraints*: Voltage of motors
- *State constraints*: Boundary of the plate, angle of the plate

[R. Waldvogel. Master Thesis ETH, 2010]

## Ball on Plate

Controller comparison: LQR vs. MPC in the presence of input constraints

Figure : LQR (red) vs MPC (blue)

# Autonomous Quadrocopter Flight

## Quadrocopters:

- Highly agile due to fast rotational dynamics
- High thrust-to-weight ratio allows for large translational accelerations
- Motion control by altering rotation rate and/or pitch of the rotors
- High thrust motors enable high performance control

## Control Problem:

- *Nonlinear system* in 6D (position, attitude)
- *Constraints*: limited thrust, rates,...
- *Task*: Hovering, trajectory tracking
- *Challenges*: Fast unstable dynamics

## Autonomous dNaNo Race Cars

### Race car:

- 1:43 scale, very light (50g) and fast
- Radio controlled
- 2.4GHz transmitter allows to run up to 40 cars

### Control Problem:

- *Nonlinear model* in 4D (position, orientation)
- *Constraints*: acceleration, steering angle, race track, other cars...
- *Task*: Optimal path planning and path following
- *Challenges*: State estimation, effects that are difficult to model/measure, e.g. slip, small sampling times

## Energy Efficient Building Control

- Buildings account for approx. 40% of global energy use
- Most energy is consumed during use of the buildings
- Building sector has large potential for cost-effective reduction of CO<sub>2</sub> emissions
- Most investments in buildings are expected to pay back through *reduced energy bills*

Greenhouse gas abatement cost curve for London buildings (2025, decision maker perspective)

# Energy Efficient Building Control

## Integrated Room Automation:

Integrated control of heating, cooling, ventilation, electrical lighting, blinds,... of a single room/zone

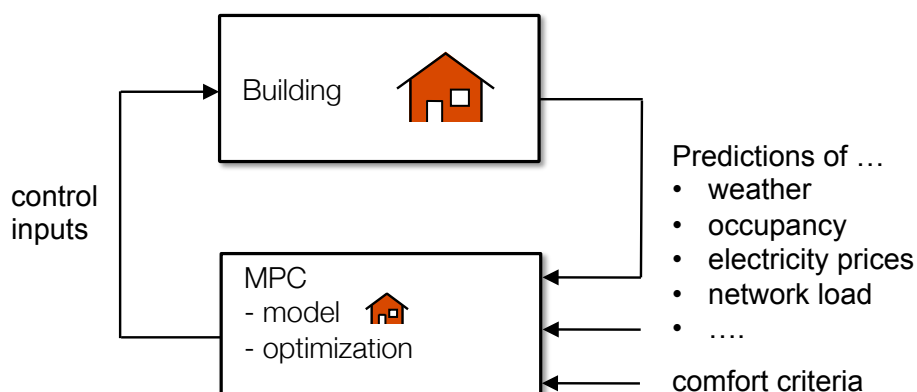

**Control Task:** Use minimum amount of energy (or money) to keep room temperature, illuminance level and CO<sub>2</sub> concentration in *prescribed comfort ranges*

[OptiControl Project, ETH. 2010; <http://www.opticontrol.ethz.ch/>]

# Energy Efficient Building Control

MPC opens the possibility to

- exploit building's *thermal storage capacity*
- use *predictions* of future disturbances, e.g. weather, for better planning
- use forecasts of electricity prices to shift electricity demand for grid-friendly behavior
- offer grid-balancing services to the power network
- ...

while respecting requirements for building usage (temperature, light, ...)

# Energy Efficient Building Control

Optimize energy efficiency using weather predictions:

- 2.4 Energy Efficient Building Control
- 2.5 Kite Power
- 2.6 Automotive Systems
- 2.7 Robotic Chameleon

## Kite Power

- Wind energy has potential to supply global energy need.
- Current wind technology is not able to exploit the potential
  - Traditional inland wind turbines are close to scaling limits
  - Economic operation only possible at a limited number of locations

*Idea:* Exploit the energy of high-altitude wind by means of light tethered wings (kites)

*Goal:* Wind power at lower cost than coal

Exploit that

- Wind speed at 800m = 1.5 × speed at 80m
- Power density = (wind speed)<sup>3</sup>

if.

## Kite Power

- Different kites proposed: flexible vs. rigid wings (different models, nonlinear)
- On board vs. ground level generator
- Ground level seems to be more viable for large-scale
- Number of lines?

### Kite control problem:

- Maximize the net generated energy
- Maintain stability of the wing
- Exploit crosswind, i.e. kites fly transverse to wind at high speed
- Satisfy physical constraints: keep the kite far away from the ground, avoid line wrapping...
- Each configuration and working phase has its own performance goal

[A. Zraggen, ETH, 2011]

## Kite Power

[Airbone Wind Energy Group. ETH, 2013; <http://control.ee.ethz.ch/~awe/>]

## Audi Smart Engine

- **Fact:** Do not accelerate if there is a traffic jam, you will only waste fuel.
- **Idea:** Use traffic forecast to regulate the speed of a car to save fuel while getting to destination on time.

- MPC regulates the desired speed (through an Automatic Cruise Control) in order to reach the destination in the most fuel-efficient way, given a

- Min and Max traffic speed forecast and road grade used in the MPC constraints and model

## Ford Autonomous Driving on Ice

- Autonomous double-lane change.
- Road forecast and nonlinear vehicle model (driving on ice) used in MPC.
- MPC controls differential braking and steering.
- Experimental results @ 72 km/h on ice.

## Volvo

- Autonomous lane keeping (minimally invasive).
- Road forecast and vehicle model used in MPC.
- MPC controls braking and steering.

[Gray, Ali, Gao, Hedrick and Borrelli. *IEEE Transactions on Intelligent Transportation Systems*, 2013]

## Robotic Chameleon

- Tracking an object (point in video) using two independent cameras.
- MPC controls cameras pan tilt and zoom to keep object in a given field of view (constraints).
- MPC uses cameras models and forecast the object position (assuming moving at constant acceleration over the prediction horizon).
- Experimental results with MPC solved at 100 Hz.

[Avin, Borrelli et al. *Autonomous Robots*, 2008]

## 3. Summary and Outlook

### 3.1 Summary

### 3.2 Literature

## Summary: MPC

At each sample time:

- Measure /estimate current state  $x(t)$
- Find the *optimal input sequence* for the entire planning window  $N$ :  
 $U_t^* = \{u_t^*, u_{t+1}^*, \dots, u_{t+N-1}^*\}$
- Implement only the *first* control action  $u_t^*$

# Summary

- Obtain a model of the system
- Design a state observer
- Define optimal control problem
- Set up optimization problem in optimization software
- Solve optimization problem to get optimal control sequence
- Verify that closed-loop system performs as desired, e.g., check performance criteria, robustness, real-time aspects,...

## Important Aspects of Model Predictive Control

### Main advantages:

- Systematic approach for handling *constraints*
- High *performance* controller

### Main challenges:

- *Implementation*  
MPC problem has to be solved in real-time, i.e. within the sampling interval of the system, and with available hardware (storage, processor,...).
- *Stability*  
Closed-loop stability, i.e. convergence, is not automatically guaranteed
- *Robustness*  
The closed-loop system is not necessarily robust against uncertainties or disturbances
- *Feasibility*  
Optimization problem may become infeasible at some future time step, i.e. there may not exist a plan satisfying all constraints

# Outlook

- Part II: Constrained Finite Time Optimal Control  
Formulating and solving the optimization problem online
- Part III: Feasibility and Stability  
Guaranteeing feasibility and stability by design
- Advanced Topics  
Tracking, Soft-Constraints, Explicit MPC, Hybrid Systems

## Cost function

$$J_0(x(0), U_0) = p(x_N) + \sum_{k=0}^{N-1} q(x_k, u_k)$$

- $U_0 \triangleq [u'_0, \dots, u'_{N-1}]'$
- Squared Euclidian norm:  $p(x_N) = x'_N P x_N$  and  $q(x_k, u_k) = x'_k Q x_k + u'_k R u_k$ .
- $p = 1$  or  $p = \infty$ :  $p(x_N) = \|P x_N\|_p$  and  $q(x_k, u_k) = \|Q x_k\|_p + \|R u_k\|_p$ .

## Constrained Finite Time Optimal Control problem (CFTOC)

$$\begin{aligned} J_0^*(x(0)) = \quad & \min_{U_0} \quad J_0(x(0), U_0) \\ \text{subj. to} \quad & x_{k+1} = A x_k + B u_k, \quad k = 0, \dots, N-1 \\ & x_k \in \mathcal{X}, \quad u_k \in \mathcal{U}, \quad k = 0, \dots, N-1 \\ & x_N \in \mathcal{X}_f \\ & x_0 = x(0) \end{aligned} \quad (1)$$

$N$  is the time horizon and  $\mathcal{X}, \mathcal{U}, \mathcal{X}_f$  are polyhedral regions.

## Table of Contents

### 1. Constrained Linear Optimal Control

#### 1.1 Problem formulation

#### 1.2 Feasible Sets

#### 1.3 Unconstrained Solution

## Feasible Sets

Set of initial states  $x(0)$  for which the optimal control problem (1) is feasible:

$$\mathcal{X}_0 = \{x_0 \in \mathbb{R}^n \mid \exists (u_0, \dots, u_{N-1}) \text{ such that } x_k \in \mathcal{X}, u_k \in \mathcal{U}, \\ k = 0, \dots, N-1, x_N \in \mathcal{X}_f, \text{ where } x_{k+1} = Ax_k + Bu_k\}$$

In general  $\mathcal{X}_i$  is the set of states  $x_i$  at time  $i$  for which (1) is feasible:

$$\mathcal{X}_i = \{x_i \in \mathbb{R}^n \mid \exists (u_i, \dots, u_{N-1}) \text{ such that } x_k \in \mathcal{X}, u_k \in \mathcal{U}, \\ k = i, \dots, N-1, x_N \in \mathcal{X}_f, \text{ where } x_{k+1} = Ax_k + Bu_k\},$$

The sets  $\mathcal{X}_i$  for  $i = 0, \dots, N$  play an important role in the the solution of the CFTOC problem. They are independent of the cost.

# Unconstrained Solution

## Results from Lectures on Days 1 & 2

For quadratic cost (squared Euclidian norm) and **no state and input constraints**:

$$\{x \in \mathcal{X}, u \in \mathcal{U}\} = \mathbb{R}^{n+m}, \mathcal{X}_f = \mathbb{R}^n$$

we have the *time-varying* linear control law

$$u^*(k) = F_k x(k) \quad k = 0, \dots, N-1.$$

If  $N \rightarrow \infty$ , we have the *time-invariant* linear control law

$$u^*(k) = F_\infty x(k) \quad k = 0, 1, \dots$$

Next we show how to compute finite time **constrained** optimal controllers.

## Problem Formulation

Quadratic cost function

$$J_0(x(0), U_0) = x_N' P x_N + \sum_{k=0}^{N-1} x_k' Q x_k + u_k' R u_k \quad (2)$$

with  $P \succeq 0$ ,  $Q \succeq 0$ ,  $R \succ 0$ .

Constrained Finite Time Optimal Control problem (CFTOC).

$$\begin{aligned} J_0^*(x(0)) = & \min_{U_0} J_0(x(0), U_0) \\ \text{subj. to} & \quad x_{k+1} = A x_k + B u_k, \quad k = 0, \dots, N-1 \\ & \quad x_k \in \mathcal{X}, \quad u_k \in \mathcal{U}, \quad k = 0, \dots, N-1 \\ & \quad x_N \in \mathcal{X}_f \\ & \quad x_0 = x(0) \end{aligned} \quad (3)$$

$N$  is the time horizon and  $\mathcal{X}$ ,  $\mathcal{U}$ ,  $\mathcal{X}_f$  are polyhedral regions.

# Table of Contents

## 2. Constrained Optimal Control: 2-Norm

### 2.1 Problem Formulation

### 2.2 Construction of the QP with substitution

### 2.3 Construction of the QP without substitution

### 2.4 2-Norm State Feedback Solution

## Construction of the QP with substitution

- **Step 1:** Rewrite the cost as (see lectures on Day 1 & 2)

$$\begin{aligned} J_0(x(0), U_0) &= U_0' H U_0 + 2x(0)' F U_0 + x(0)' Y x(0) \\ &= [U_0' \ x(0)'] \begin{bmatrix} H & F' \\ F & Y \end{bmatrix} [U_0' \ x(0)']' \end{aligned}$$

Note:  $\begin{bmatrix} H & F' \\ F & Y \end{bmatrix} \succeq 0$  since  $J_0(x(0), U_0) \geq 0$  by assumption.

- **Step 2:** Rewrite the constraints compactly as (details provided on the next slide)

$$G_0 U_0 \leq w_0 + E_0 x(0)$$

- **Step 3:** Rewrite the optimal control problem as

$$\begin{aligned} J_0^*(x(0)) &= \min_{U_0} [U_0' \ x(0)'] \begin{bmatrix} H & F' \\ F & Y \end{bmatrix} [U_0' \ x(0)']' \\ \text{subj. to} \quad & G_0 U_0 \leq w_0 + E_0 x(0) \end{aligned}$$

## Solution

$$J_0^*(x(0)) = \min_{U_0} [U_0' \ x(0)'] \begin{bmatrix} H & F' \\ F & Y \end{bmatrix} [U_0' \ x(0)']'$$

$$\text{subj. to } G_0 U_0 \leq w_0 + E_0 x(0)$$

For a given  $x(0)$   $U_0^*$  can be found via a QP solver.

## Construction of QP constraints with substitution

If  $\mathcal{X}$ ,  $\mathcal{U}$  and  $\mathcal{X}_f$  are given by:

$$\mathcal{X} = \{x \mid A_x x \leq b_x\} \quad \mathcal{U} = \{u \mid A_u u \leq b_u\} \quad \mathcal{X}_f = \{x \mid A_f x \leq b_f\}$$

Then  $G_0$ ,  $E_0$  and  $w_0$  are defined as follows

$$G_0 = \begin{bmatrix} A_u & 0 & \dots & 0 \\ 0 & A_u & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & A_u \\ 0 & 0 & \dots & 0 \\ A_x B & 0 & \dots & 0 \\ A_x A B & A_x B & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ A_f A^{N-1} B & A_f A^{N-2} B & \dots & A_f B \end{bmatrix}, E_0 = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ -A_x \\ -A_x A \\ -A_x A^2 \\ \vdots \\ -A_f A^N \end{bmatrix}, w_0 = \begin{bmatrix} b_u \\ b_u \\ \vdots \\ b_u \\ b_x \\ b_x \\ b_x \\ \vdots \\ b_f \end{bmatrix}$$

# Table of Contents

- 2. Constrained Optimal Control: 2-Norm
  - 2.1 Problem Formulation
  - 2.2 Construction of the QP with substitution
  - 2.3 Construction of the QP without substitution
  - 2.4 2-Norm State Feedback Solution

## Construction of the QP without substitution

To obtain the QP problem

$$J_0^*(x(0)) = \min_{U_0} [U_0' \ x(0)'] \begin{bmatrix} H & F' \\ F & Q \end{bmatrix} [U_0' \ x(0)']'$$

$$\text{subj. to} \quad G_0 U_0 \leq w_0 + E_0 x(0)$$

we have substituted the state equations

$$x_{k+1} = Ax_k + Bu_k$$

into the state constraints  $x_k \in \mathcal{X}$ .

It is often more efficient to keep the explicit equality constraints.

## Construction of the QP without substitution

We transform the CFTOC problem into the QP problem

$$\begin{aligned} J_0^*(x(0)) = \min_z \quad & [z' \ x(0)'] \begin{bmatrix} \bar{H} & 0 \\ 0 & Q \end{bmatrix} [z' \ x(0)']' \\ \text{subj. to} \quad & G_{0,\text{in}} z \leq w_{0,\text{in}} + E_{0,\text{in}} x(0) \\ & G_{0,\text{eq}} z = E_{0,\text{eq}} x(0) \end{aligned}$$

■ Define variable:

$$z = [x'_1 \ \dots \ x'_N \ u'_0 \ \dots \ u'_{N-1}]'$$

■ Equalities from system dynamics  $x_{k+1} = Ax_k + Bu_k$ :

$$G_{0,\text{eq}} = \begin{bmatrix} I & & & & -B \\ -A & I & & & -B \\ & -A & I & & -B \\ & & \ddots & \ddots & \\ & & & -A & I & -B \end{bmatrix}, E_{0,\text{eq}} = \begin{bmatrix} A \\ 0 \\ \vdots \\ 0 \end{bmatrix}$$

## Construction of the QP without substitution

If  $\mathcal{X}$ ,  $\mathcal{U}$  and  $\mathcal{X}_f$  are given by:

$$\mathcal{X} = \{x \mid A_x x \leq b_x\} \quad \mathcal{U} = \{u \mid A_u u \leq b_u\} \quad \mathcal{X}_f = \{x \mid A_f x \leq b_f\}$$

Then matrices  $G_{0,\text{in}}$ ,  $w_{0,\text{in}}$  and  $E_{0,\text{in}}$  are:

$$G_{0,\text{in}} = \begin{bmatrix} 0 & & & & 0 & & & & \\ & A_x & & & 0 & & & & \\ & & \ddots & & & & & & \\ & & & A_x & & & & 0 & \\ & & & & A_f & & & & 0 \\ 0 & \cdots & & & & A_u & & & \\ & 0 & & & & & A_u & & \\ & & \ddots & & & & & \ddots & \\ & & & 0 & & & & & A_u \\ & & & & 0 & & & & \end{bmatrix} \quad w_{0,\text{in}} = \begin{bmatrix} b_x \\ b_x \\ \vdots \\ b_x \\ b_f \\ b_u \\ b_u \\ \vdots \\ b_u \\ b_u \end{bmatrix}$$

$$E_{0,\text{in}} = [-A'_x \ 0 \ \dots \ 0]'$$

## Construction of the QP without substitution

Build cost function from MPC cost  $x'_N P x_N + \sum_{k=0}^{N-1} x'_k Q x_k + u'_k R u_k$

$$\bar{H} = \begin{bmatrix} Q & & & & \\ & \ddots & & & \\ & & Q & & \\ - & - & - & P & - \\ & & & R & \\ & & & & \ddots \\ & & & & & R \end{bmatrix}$$

Matlab hint:

```
barH = blkdiag(kron(eye(N-1),Q), P, kron(eye(N),R))
```

## Table of Contents

### 2. Constrained Optimal Control: 2-Norm

#### 2.1 Problem Formulation

#### 2.2 Construction of the QP with substitution

#### 2.3 Construction of the QP without substitution

#### 2.4 2-Norm State Feedback Solution

## 2-Norm State Feedback Solution

Start from QP with substitution.

- **Step 1:** Define  $z \triangleq U_0 + H^{-1}F'x(0)$  and transform the problem into

$$\hat{J}^*(x(0)) = \min_z z'Hz$$

$$\text{subj. to } G_0z \leq w_0 + S_0x(0),$$

where  $S_0 \triangleq E_0 + G_0H^{-1}F'$ , and

$$\hat{J}^*(x(0)) = J_0^*(x(0)) - x(0)'(Y - FH^{-1}F')x(0).$$

The CFTOC problem is now a **multiparametric quadratic program (mp-QP)**.

- **Step 2:** Solve the mp-QP to get explicit solution  $z^*(x(0))$
- **Step 3:** Obtain  $U_0^*(x(0))$  from  $z^*(x(0))$

## 2-Norm State Feedback Solution

### Main Results

- 1 The **Open loop optimal control function** can be obtained by solving the mp-QP problem and calculating  $U_0^*(x(0))$ ,  $\forall x(0) \in \mathcal{X}_0$  as  $U_0^* = z^*(x(0)) - H^{-1}F'x(0)$ .

- 2 The first component of the multiparametric solution has the form

$$u^*(0) = f_0(x(0)), \quad \forall x(0) \in \mathcal{X}_0,$$

$f_0 : \mathbb{R}^n \rightarrow \mathbb{R}^m$ , is continuous and PieceWise Affine on Polyhedra

$$f_0(x) = F_0^i x + g_0^i \quad \text{if } x \in CR_0^i, \quad i = 1, \dots, N_0^r$$

- 3 The polyhedral sets  $CR_0^i = \{x \in \mathbb{R}^n | H_0^i x \leq K_0^i\}$ ,  $i = 1, \dots, N_0^r$  are a partition of the feasible polyhedron  $\mathcal{X}_0$ .

- 4 The value function  $J_0^*(x(0))$  is convex and piecewise quadratic on polyhedra.

## Example

Consider the double integrator

$$\begin{cases} x(t+1) &= \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(t) \\ y(t) &= \begin{bmatrix} 1 & 0 \end{bmatrix} x(t) \end{cases}$$

subject to constraints

$$-1 \leq u(k) \leq 1, \quad k = 0, \dots, 5$$

$$\begin{bmatrix} -10 \\ -10 \end{bmatrix} \leq x(k) \leq \begin{bmatrix} 10 \\ 10 \end{bmatrix}, \quad k = 0, \dots, 5$$

Compute the **state feedback** optimal controller  $u^*(0)(x(0))$  solving the CFTOC problem with  $N = 6$ ,  $Q = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ ,  $R = 0.1$ ,  $P$  the solution of the ARE,  $\mathcal{X}_f = \mathbb{R}^2$ .

## Example

Figure : Partition of the state space for the affine control law  $u^*(0)$  ( $N_0^r = 13$ )

3.1 Problem Formulation

3.2 Construction of the LP with substitution

## Problem Formulation

Piece-wise linear cost function

$$J_0(x(0), U_0) := \|Px_N\|_p + \sum_{k=0}^{N-1} \|Qx_k\|_p + \|Ru_k\|_p \quad (4)$$

with  $p = 1$  or  $p = \infty$ ,  $P$ ,  $Q$ ,  $R$  full column rank matrices

Constrained Finite Time Optimal Control Problem (CFTOC)

$$\begin{aligned} J_0^*(x(0)) = & \min_{U_0} J_0(x(0), U_0) \\ \text{subj. to} & \quad x_{k+1} = Ax_k + Bu_k, \quad k = 0, \dots, N-1 \\ & \quad x_k \in \mathcal{X}, \quad u_k \in \mathcal{U}, \quad k = 0, \dots, N-1 \\ & \quad x_N \in \mathcal{X}_f \\ & \quad x_0 = x(0) \end{aligned} \quad (5)$$

$N$  is the time horizon and  $\mathcal{X}$ ,  $\mathcal{U}$ ,  $\mathcal{X}_f$  are polyhedral regions.

## Table of Contents

### 3. Constrained Optimal Control: 1-Norm and $\infty$ -Norm

#### 3.1 Problem Formulation

#### 3.2 Construction of the LP with substitution

## Construction of the LP with substitution

Recall that the  $\infty$ -norm problem can be equivalently formulated as

$$\begin{aligned}
 \min_{z_0} \quad & \varepsilon_0^x + \dots + \varepsilon_N^x + \varepsilon_0^u + \dots + \varepsilon_{N-1}^u \\
 \text{subj. to} \quad & -\mathbf{1}_n \varepsilon_k^x \leq \pm Q \left[ A^k x_0 + \sum_{j=0}^{k-1} A^j B u_{k-1-j} \right], \\
 & -\mathbf{1}_r \varepsilon_N^x \leq \pm P \left[ A^N x_0 + \sum_{j=0}^{N-1} A^j B u_{N-1-j} \right], \\
 & -\mathbf{1}_m \varepsilon_k^u \leq \pm R u_k, \\
 & A^k x_0 + \sum_{j=0}^{k-1} A^j B u_{k-1-j} \in \mathcal{X}, \quad u_k \in \mathcal{U}, \\
 & A^N x_0 + \sum_{j=0}^{N-1} A^j B u_{N-1-j} \in \mathcal{X}_f, \\
 & k = 0, \dots, N-1 \\
 & x_0 = x(0)
 \end{aligned}$$

## Construction of the LP with substitution

The problem results in the following standard LP

$$\begin{aligned}
 \min_{z_0} \quad & c'_0 z_0 \\
 \text{subj. to} \quad & \bar{G}_0 z_0 \leq \bar{w}_0 + \bar{S}_0 x(0)
 \end{aligned}$$

where  $z_0 := \{\varepsilon_0^x, \dots, \varepsilon_N^x, \varepsilon_0^u, \dots, \varepsilon_{N-1}^u, u'_0, \dots, u'_{N-1}\} \in \mathbb{R}^s$ ,  
 $s \triangleq (m+1)N + N + 1$  and

$$\bar{G}_0 = \begin{bmatrix} G_\varepsilon & 0 \\ 0 & G_0 \end{bmatrix}, \quad \bar{S}_0 = \begin{bmatrix} S_\varepsilon \\ S_0 \end{bmatrix}, \quad \bar{w}_0 = \begin{bmatrix} w_\varepsilon \\ w_0 \end{bmatrix}$$

For a given  $x(0)$   $U_0^*$  can be obtained via an LP solver (the 1-norm case is similar).

# Table of Contents

## 3. Constrained Optimal Control: 1-Norm and $\infty$ -Norm

### 3.1 Problem Formulation

### 3.2 Construction of the LP with substitution

## 1- / $\infty$ -Norm State Feedback Solution

### Main Results

- 1 The **Open loop optimal control function** can be obtained by solving the mp-LP problem and calculating  $z_0^*(x(0))$
- 2 The component  $u_0^* = [0 \dots 0 \ I_m \ 0 \dots 0] z_0^*(x(0))$  of the multiparametric solution has the form

$$u^*(0) = f_0(x(0)), \quad \forall x(0) \in \mathcal{X}_0,$$

$f_0 : \mathbb{R}^n \rightarrow \mathbb{R}^m$ , is continuous and PieceWise Affine on Polyhedra

$$f_0(x) = F_0^i x + g_0^i \quad \text{if} \quad x \in CR_0^i, \quad i = 1, \dots, N_0^r$$

- 3 The polyhedral sets  $CR_0^i = \{x \in \mathbb{R}^n | H_0^i x \leq K_0^i\}$ ,  $i = 1, \dots, N_0^r$  are a partition of the feasible polyhedron  $\mathcal{X}_0$ .
- 4 In case of multiple optimizers a PieceWise Affine control law exists.
- 5 The value function  $J_0^*(x(0))$  is convex and piecewise linear on polyhedra.

## Infinite Time Constrained Optimal Control (what we would like to solve)

$$\begin{aligned}
 J_0^*(x(0)) &= \min \sum_{k=0}^{\infty} q(x_k, u_k) \\
 \text{s.t. } &x_{k+1} = Ax_k + Bu_k, k = 0, \dots, N-1 \\
 &x_k \in \mathcal{X}, u_k \in \mathcal{U}, k = 0, \dots, N-1 \\
 &x_0 = x(0)
 \end{aligned}$$

- **Stage cost**  $q(x, u)$  describes “cost” of being in state  $x$  and applying input  $u$
- Optimizing over a trajectory provides a **tradeoff between short- and long-term benefits** of actions
- We’ll see that such a control law has many beneficial properties...  
... but we can’t compute it: there are an **infinite number of variables**

# Receding Horizon Control (what we can sometimes solve)

$$\begin{aligned}
 J_t^*(x(t)) = \min_{U_t} \quad & p(x_{t+N}) + \sum_{k=0}^{N-1} q(x_{t+k}, u_{t+k}) \\
 \text{subj. to} \quad & x_{t+k+1} = Ax_{t+k} + Bu_{t+k}, \quad k = 0, \dots, N-1 \\
 & x_{t+k} \in \mathcal{X}, \quad u_{t+k} \in \mathcal{U}, \quad k = 0, \dots, N-1 \\
 & x_{t+N} \in \mathcal{X}_f \\
 & x_t = x(t)
 \end{aligned} \tag{1}$$

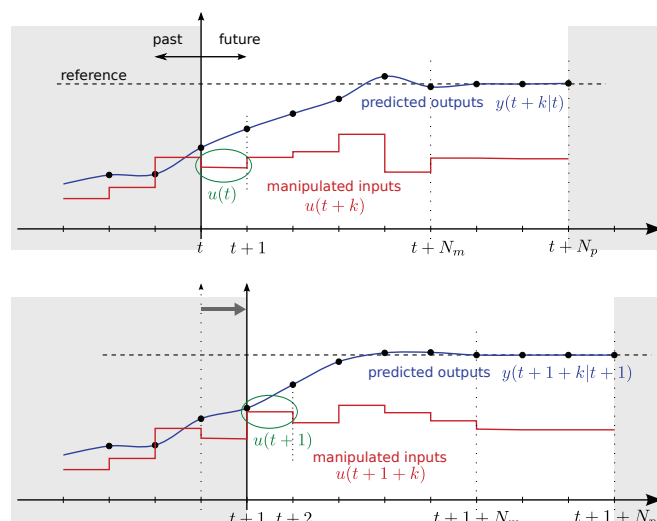

where  $\mathcal{U}_t = \{u_t, \dots, u_{t+N-1}\}$ .

Truncate after a finite horizon:

- $p(x_{t+N})$  : Approximates the 'tail' of the cost
- $\mathcal{X}_f$  : Approximates the 'tail' of the constraints

## On-line Receding Horizon Control

- 1 At each sampling time, solve a **CFTOC**.
- 2 Apply the optimal input **only during**  $[t, t+1]$
- 3 At  $t+1$  solve a CFTOC over a **shifted horizon** based on new state measurements
- 4 The resultant controller is referred to as **Receding Horizon Controller (RHC)** or **Model Predictive Controller (MPC)**.

# On-line Receding Horizon Control

- 1) MEASURE the state  $x(t)$  at time instance  $t$
- 2) OBTAIN  $U_t^*(x(t))$  by solving the optimization problem in (1)
- 3) IF  $U_t^*(x(t)) = \emptyset$  THEN 'problem infeasible' STOP
- 4) APPLY the first element  $u_t^*$  of  $U_t^*$  to the system
- 5) WAIT for the new sampling time  $t + 1$ , GOTO 1)

Note that, we need a constrained optimization solver for step 2).

## Table of Contents

5. Stability and Invariance of MPC
6. Feasibility and Stability
  - 6.1 Proof for  $\mathcal{X}_f = 0$
  - 6.2 General Terminal Sets
  - 6.3 Example
7. Extension to Nonlinear MPC

## History of MPC

- **A. I. Propoi, 1963**, “Use of linear programming methods for synthesizing sampled-data automatic systems”, *Automation and Remote Control*.
- **J. Richalet et al., 1978** “Model predictive heuristic control- application to industrial processes”. *Automatica*, 14:413-428.
  - known as **IDCOM (Identification and Command)**
  - impulse response model for the plant, linear in inputs or internal variables (**only stable plants**)
  - quadratic performance objective over a finite prediction horizon
  - future plant output behavior specified by a reference trajectory
  - **ad hoc** input and output constraints
  - optimal inputs computed using a heuristic iterative algorithm, interpreted as the dual of identification
  - controller was not a transfer function, hence called **heuristic**

## History of MPC

- 1970s: Cutler suggested MPC in his PhD proposal at the University of Houston in 1969 and introduced it later at Shell under the name Dynamic Matrix Control. **C. R. Cutler, B. L. Ramaker, 1979** “Dynamic matrix control – a computer control algorithm”. *AIChE National Meeting*, Houston, TX.
  - successful in the petro-chemical industry
  - linear step response model for the plant
  - quadratic performance objective over a finite prediction horizon
  - future plant output behavior specified by trying to follow the set-point as closely as possible
  - input and output constraints included in the formulation
  - optimal inputs computed as the solution to a least-squares problem
  - **ad hoc** input and output constraints. Additional equation added online to account for constraints. Hence a **dynamic matrix** in the least squares problem.
- **C. Cutler, A. Morshedi, J. Haydel, 1983**. “An industrial perspective on advanced control”. *AIChE Annual Meeting*, Washington, DC.
  - Standard QP problem formulated in order to systematically account for constraints.

# History of MPC

- Mid 1990s: extensive theoretical effort devoted to provide conditions for guaranteeing feasibility and closed-loop stability
- 2000s: development of tractable robust MPC approaches; nonlinear and hybrid MPC; MPC for very fast systems
- 2010s: stochastic MPC; distributed large-scale MPC; economic MPC

## Table of Contents

1. Basic Ideas of Predictive Control
2. History of MPC
3. Receding Horizon Control Notation
4. MPC Features
5. Stability and Invariance of MPC
6. Feasibility and Stability
  - 6.1 Proof for  $\mathcal{X}_f = 0$
  - 6.2 General Terminal Sets
  - 6.3 Example
7. Extension to Nonlinear MPC

## RHC Notation

$$\begin{aligned}x(t+1) &= Ax(t) + Bu(t) \\ y(t) &= Cx(t)\end{aligned}$$

$$x(t) \in \mathcal{X}, \quad u(t) \in \mathcal{U}, \quad \forall t \geq 0$$

### The CFTOC Problem

$$\begin{aligned}J_t^*(x(t)) &= \min_{U_{t \rightarrow t+N|t}} p(x_{t+N|t}) + \sum_{k=0}^{N-1} q(x_{t+k|t}, u_{t+k|t}) \\ \text{subj. to } & x_{t+k+1|t} = Ax_{t+k|t} + Bu_{t+k|t}, \quad k = 0, \dots, N-1 \\ & x_{t+k|t} \in \mathcal{X}, \quad u_{t+k|t} \in \mathcal{U}, \quad k = 0, \dots, N-1 \\ & x_{t+N|t} \in \mathcal{X}_f \\ & x_{t|t} = x(t)\end{aligned}$$

with  $U_{t \rightarrow t+N|t} = \{u_{t|t}, \dots, u_{t+N-1|t}\}$ .

## RHC Notation

- $x(t)$  is the state of the system at time  $t$ .
- $x_{t+k|t}$  is the state of the model at time  $t+k$ , predicted at time  $t$  obtained by starting from the current state  $x_{t|t} = x(t)$  and applying to the system model

$$x_{t+1|t} = Ax_{t|t} + Bu_{t|t}$$

the input sequence  $u_{t|t}, \dots, u_{t+k-1|t}$ .

- For instance,  $x_{3|1}$  represents the predicted state at time 3 when the prediction is done at time  $t=1$  starting from the current state  $x(1)$ . It is different, in general, from  $x_{3|2}$  which is the predicted state at time 3 when the prediction is done at time  $t=2$  starting from the current state  $x(2)$ .
- Similarly  $u_{t+k|t}$  is read as “the input  $u$  at time  $t+k$  computed at time  $t$ ”.

## RHC Notation

- Let  $U_{t \rightarrow t+N|t}^* = \{u_{t|t}^*, \dots, u_{t+N-1|t}^*\}$  be the optimal solution. The first element of  $U_{t \rightarrow t+N|t}^*$  is applied to system

$$u(t) = u_{t|t}^*(x(t)).$$

- The CFTOC problem is reformulated and solved at time  $t+1$ , based on the new state  $x_{t+1|t+1} = x(t+1)$ .

Receding horizon control law

$$f_t(x(t)) = u_{t|t}^*(x(t))$$

Closed loop system

$$x(t+1) = Ax(t) + Bf_t(x(t)) \triangleq f_{cl}(x(t)), \quad t \geq 0$$

## RHC Notation: Time-invariant Systems

As the system, the constraints and the cost function are time-invariant, the solution  $f_t(x(t))$  becomes a time-invariant function of the initial state  $x(t)$ . Thus, we can simplify the notation as

$$J_0^*(x(t)) = \min_{U_0} p(x_N) + \sum_{k=0}^{N-1} q(x_k, u_k)$$

subj. to

$$\begin{aligned} x_{k+1} &= Ax_k + Bu_k, \quad k = 0, \dots, N-1 \\ x_k &\in \mathcal{X}, \quad u_k \in \mathcal{U}, \quad k = 0, \dots, N-1 \\ x_N &\in \mathcal{X}_f \\ x_0 &= x(t) \end{aligned}$$

where  $U_0 = \{u_0, \dots, u_{N-1}\}$ .

The control law and closed loop system are **time-invariant** as well, and we write  $f_0(x_0)$  for  $f_t(x(t))$ .

# Table of Contents

## MPC Features

### Pros

- Any model
  - linear
  - nonlinear
  - single/multivariable
  - time delays
  - constraints
- Any objective:
  - sum of squared errors
  - sum of absolute errors (i.e., integral)
  - worst error over time
  - economic objective

### Cons

- Computationally demanding in the general case
- May or may not be stable
- May or may not be feasible

## Example: Cessna Citation Aircraft

Linearized continuous-time model:

(at altitude of 5000m and a speed of 128.2 m/sec)

$$\dot{x} = \begin{bmatrix} -1.2822 & 0 & 0.98 & 0 \\ 0 & 0 & 1 & 0 \\ -5.4293 & 0 & -1.8366 & 0 \\ -128.2 & 128.2 & 0 & 0 \end{bmatrix} x + \begin{bmatrix} -0.3 \\ 0 \\ -17 \\ 0 \end{bmatrix} u$$

$$y = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} x$$

- Input: elevator angle
- States:  $x_1$ : angle of attack,  $x_2$ : pitch angle,  $x_3$ : pitch rate,  $x_4$ : altitude
- Outputs: pitch angle and altitude
- Constraints: elevator angle  $\pm 0.262\text{rad}$  ( $\pm 15^\circ$ ), elevator rate  $\pm 0.524\text{rad}$  ( $\pm 60^\circ$ ), pitch angle  $\pm 0.349$  ( $\pm 39^\circ$ )

Open-loop response is unstable (open-loop poles:  $0, 0, -1.5594 \pm 2.29i$ )

## LQR and Linear MPC with Quadratic Cost

- Quadratic cost
- Linear system dynamics
- Linear constraints on inputs and states

*LQR*

$$J_\infty(x(t)) = \min \sum_{k=0}^{\infty} x_k^T Q x_k + u_k^T R u_k$$

$$\text{s.t. } x_{k+1} = A x_k + B u_k$$

$$x_0 = x(t)$$

*MPC*

$$J_0^*(x(t)) = \min_{U_0} \sum_{k=0}^{N-1} x_k^T Q x_k + u_k^T R u_k$$

$$\text{s.t. } x_{k+1} = A x_k + B u_k$$

$$x_k \in \mathcal{X}, u_k \in \mathcal{U}$$

$$x_0 = x(t)$$

Assume:  $Q = Q^T \succeq 0$ ,  $R = R^T \succ 0$

## Example: LQR with saturation

Linear quadratic regulator with saturated inputs.

At time  $t = 0$  the plane is flying with a deviation of 10m of the desired altitude, i.e.  $x_0 = [0; 0; 0; 10]$

Problem parameters:

Sampling time 0.25sec,  
 $Q = I, R = 10$

- Closed-loop system is unstable
- Applying LQR control and saturating the controller can lead to instability!

## Example: MPC with Bound Constraints on Inputs

MPC controller with input constraints  $|u_i| \leq 0.262$

Problem parameters:

Sampling time 0.25sec,  
 $Q = I, R = 10, N = 10$

The MPC controller uses the knowledge that the elevator will saturate, but it does not consider the rate constraints.

⇒ System does not converge to desired steady-state but to a limit cycle

## Example: MPC with all Input Constraints

MPC controller with input constraints  $|u_i| \leq 0.262$   
 and rate constraints  $|\dot{u}_i| \leq 0.349$   
 approximated by  $|u_k - u_{k-1}| \leq 0.349 T_s$

Problem parameters:

Sampling time 0.25sec,  
 $Q = I, R = 10, N = 10$

The MPC controller considers all constraints on the actuator

- Closed-loop system is stable
- Efficient use of the control authority

## Example: Inclusion of state constraints

MPC controller with input constraints  $|u_i| \leq 0.262$   
 and rate constraints  $|\dot{u}_i| \leq 0.349$   
 approximated by  $|u_k - u_{k-1}| \leq 0.349 T_s$

Problem parameters:

Sampling time 0.25sec,  
 $Q = I, R = 10, N = 10$

Increase step:

At time  $t = 0$  the plane is flying with a deviation of 100m of the desired altitude, i.e.  $x_0 = [0; 0; 0; 100]$

- Pitch angle too large during transient

## Example: Inclusion of state constraints

MPC controller with input constraints  $|u_i| \leq 0.262$   
 and rate constraints  $|\dot{u}_i| \leq 0.349$   
 approximated by  $|u_k - u_{k-1}| \leq 0.349 T_s$

Problem parameters:

Sampling time 0.25sec,  
 $Q = I, R = 10, N = 10$

Add state constraints for passenger comfort:

$$|x_2| \leq 0.349$$

## Example: Short horizon

MPC controller with input constraints  $|u_i| \leq 0.262$   
 and rate constraints  $|\dot{u}_i| \leq 0.349$   
 approximated by  $|u_k - u_{k-1}| \leq 0.349 T_s$

Problem parameters:

Sampling time 0.25sec,  
 $Q = I, R = 10, N = 4$

Decrease in the prediction horizon causes loss of the stability properties

## Example: Short horizon

MPC controller with input constraints  $|u_i| \leq 0.262$   
 and rate constraints  $|\dot{u}_i| \leq 0.349$   
 approximated by  $|u_k - u_{k-1}| \leq 0.349 T_s$

Problem parameters:

Sampling time 0.25sec,  
 $Q = I$ ,  $R = 10$ ,  $N = 4$

Inclusion of terminal cost and constraint provides stability

## Loss of Feasibility and Stability

What can go wrong with “standard” MPC?

- No feasibility guarantee, i.e., the MPC problem may not have a solution
- No stability guarantee, i.e., trajectories may not converge to the origin

### Example: Loss of feasibility - Double Integrator

Consider the double integrator

$$\begin{cases} x(t+1) &= \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(t) \\ y(t) &= \begin{bmatrix} 1 & 0 \end{bmatrix} x(t) \end{cases}$$

subject to the input constraints

$$-0.5 \leq u(t) \leq 0.5$$

and the state constraints

$$\begin{bmatrix} -5 \\ -5 \end{bmatrix} \leq x(t) \leq \begin{bmatrix} 5 \\ 5 \end{bmatrix}.$$

Compute a receding horizon controller with quadratic objective with

$$N = 3, \quad P = Q = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad R = 10.$$

## Example: Loss of feasibility - Double Integrator

The QP problem associated with the RHC is

$$H = \begin{bmatrix} 13.50 & -10.00 & -0.50 \\ -10.00 & 22.00 & -10.00 \\ -0.50 & -10.00 & 31.50 \end{bmatrix}, \quad F = \begin{bmatrix} -10.50 & 10.00 & -0.50 \\ -20.50 & 10.00 & 9.50 \end{bmatrix}, \quad Y = \begin{bmatrix} 14.50 & 23.50 \\ 23.50 & 54.50 \end{bmatrix}$$

$$G_0 = \begin{bmatrix} 0.50 & -1.00 & 0.50 \\ -0.50 & 1.00 & -0.50 \\ -0.50 & 0.00 & 0.50 \\ -0.50 & 0.00 & -0.50 \\ 0.50 & 0.00 & -0.50 \\ 0.50 & 0.00 & 0.50 \\ -1.00 & 0.00 & 0.00 \\ 0.00 & -1.00 & 0.00 \\ 1.00 & 0.00 & 0.00 \\ 0.00 & 1.00 & 0.00 \\ 0.00 & 0.00 & -1.00 \\ 0.00 & 0.00 & 1.00 \\ 0.00 & 0.00 & 0.00 \\ -0.50 & 0.00 & 0.50 \\ 0.00 & 0.00 & 0.00 \\ 0.50 & 0.00 & -0.50 \\ -0.50 & 0.00 & 0.50 \\ 0.50 & 0.00 & -0.50 \\ 0.00 & 0.00 & 0.00 \\ 0.00 & 0.00 & 0.00 \\ 0.00 & 0.00 & 0.00 \\ 0.00 & 0.00 & 0.00 \end{bmatrix}, \quad E_0 = \begin{bmatrix} 0.50 & 0.50 \\ -0.50 & -0.50 \\ 0.50 & 0.50 \\ -0.50 & -0.50 \\ -0.50 & -0.50 \\ 0.50 & 0.50 \\ 0.00 & 0.00 \\ 0.00 & 0.00 \\ 0.00 & 0.00 \\ 0.00 & 0.00 \\ 0.00 & 0.00 \\ 1.00 & 1.00 \\ -0.50 & -0.50 \\ -1.00 & -1.00 \\ 0.50 & 0.50 \\ -0.50 & -1.50 \\ 0.50 & 1.50 \\ 1.00 & 0.00 \\ 0.00 & 1.00 \\ -1.00 & 0.00 \\ 0.00 & -1.00 \end{bmatrix}, \quad w_0 = \begin{bmatrix} 0.50 \\ 0.50 \\ 5.00 \\ 5.00 \\ 5.00 \\ 5.00 \\ 5.00 \\ 5.00 \\ 5.00 \\ 5.00 \\ 0.50 \\ 0.50 \\ 5.00 \\ 5.00 \\ 5.00 \\ 5.00 \\ 0.50 \\ 0.50 \\ 5.00 \\ 5.00 \\ 5.00 \\ 5.00 \\ 5.00 \end{bmatrix}$$

## Example: Loss of feasibility - Double Integrator

- 1) MEASURE the state  $x(t)$  at time instance  $t$
- 2) OBTAIN  $U_0^*(x(t))$  by solving the optimization problem in (1)
- 3) IF  $U_0^*(x(t)) = \emptyset$  THEN 'problem infeasible' STOP
- 4) APPLY the first element  $u_0^*$  of  $U_0^*$  to the system
- 5) WAIT for the new sampling time  $t + 1$ , GOTO 1)

Depending on initial condition, closed loop trajectory may lead to states for which optimization problem is infeasible.

## Example: Loss of feasibility - Double Integrator

Boxes (Circles) are initial points leading (not leading) to feasible closed-loop trajectories

## Example: Feasibility and stability are function of tuning

Unstable system 
$$x(t+1) = \begin{bmatrix} 2 & 1 \\ 0 & 0.5 \end{bmatrix} x(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u(t)$$

Input constraints  $-1 \leq u(t) \leq 1$

Parameters:  $Q = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

State constraints  $\begin{bmatrix} -10 \\ -10 \end{bmatrix} \leq x(t) \leq \begin{bmatrix} 10 \\ 10 \end{bmatrix}$

Investigate the stability properties for different horizons  $N$  and weights  $R$  by solving the finite-horizon MPC problem in a receding horizon fashion...

## Example: Feasibility and stability are function of tuning

①  $R = 10, N = 2$ : all trajectories unstable.

②  $R = 2, N = 3$ : some trajectories stable.

③  $R = 1, N = 4$ : more stable trajectories.

\* Initial points with convergent trajectories

○ Initial points that diverge

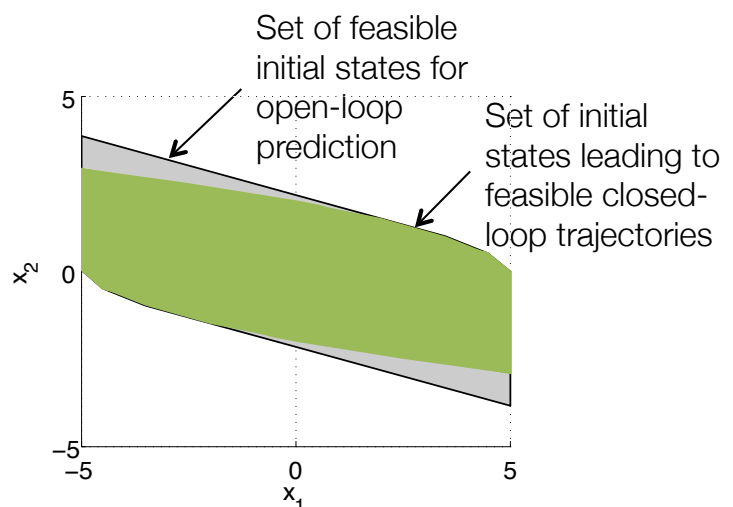

Green lines denote the set of all feasible initial points. They depend on the horizon  $N$  but not on the cost  $R \Rightarrow$  Parameters have complex effect and trajectories. 

## Summary: Feasibility and Stability

Problems originate from the use of a 'short sighted' strategy

$\Rightarrow$  Finite horizon causes deviation between the open-loop prediction and the closed-loop system:

Ideally we would solve the MPC problem with an infinite horizon, but that is computationally intractable

$\Rightarrow$  Design finite horizon problem such that it approximates the infinite horizon

## Summary: Feasibility and Stability

### ■ Infinite-Horizon

If we solve the RHC problem for  $N = \infty$  (as done for LQR), then the open loop trajectories are the same as the closed loop trajectories. Hence

- If problem is feasible, the closed loop trajectories will be always feasible
- If the cost is finite, then states and inputs will converge asymptotically to the origin

### ■ Finite-Horizon

RHC is “short-sighted” strategy approximating infinite horizon controller. But

- **Feasibility.** After some steps the finite horizon optimal control problem may become infeasible. (Infeasibility occurs without disturbances and model mismatch!)
- **Stability.** The generated control inputs may not lead to trajectories that converge to the origin.

## Feasibility and stability in MPC - Solution

**Main idea:** Introduce terminal cost and constraints to explicitly ensure feasibility and stability:

$$\begin{aligned}
 J_0^*(x_0) = & \min_{U_0} \quad p(x_N) + \sum_{k=0}^{N-1} q(x_k, u_k) && \text{Terminal Cost} \\
 & \text{subj. to} \\
 & x_{k+1} = Ax_k + Bu_k, \quad k = 0, \dots, N-1 \\
 & x_k \in \mathcal{X}, \quad u_k \in \mathcal{U}, \quad k = 0, \dots, N-1 \\
 & x_N \in \mathcal{X}_f && \text{Terminal Constraint} \\
 & x_0 = x(t)
 \end{aligned}$$

$p(\cdot)$  and  $\mathcal{X}_f$  are chosen to **mimic an infinite horizon**.

# Feasibility and Stability of MPC: Proof

Main steps:

- Prove recursive feasibility by showing the existence of a feasible control sequence at all time instants when starting from a feasible initial point
- Prove stability by showing that the optimal cost function is a Lyapunov function

Two cases:

- 1 Terminal constraint at zero:  $x_N = 0$
- 2 Terminal constraint in some (convex) set:  $x_N \in \mathcal{X}_f$

General notation:

$$J_0^*(x_0) = \min_{U_0} \underbrace{p(x_N)}_{\text{terminal cost}} + \sum_{i=0}^{N-1} \underbrace{q(x_i, u_i)}_{\text{stage cost}}$$

Quadratic case:  $q(x_i, u_i) = x_i^T Q x_i + u_i^T R u_i$ ,  $p(x_N) = x_N^T P x_N$

## Stability of MPC - Zero terminal state constraint

Terminal constraint:  $x_N \in \mathcal{X}_f = 0$

- Assume feasibility of  $x_0$  and let  $\{u_0^*, u_1^*, \dots, u_{N-1}^*\}$  be the optimal control sequence computed at  $x_0$  and  $\{x(0), x_1, \dots, x_N\}$  be the corresponding state trajectory
- Apply  $u_0^*$  and let system evolve to  $x(1) = Ax_0 + Bu_0^*$
- At  $x(1)$  the control sequence  $\{u_1^*, u_2^*, \dots, u_{N-1}^*, 0\}$  is feasible (apply 0 control input  $\Rightarrow x_{N+1} = 0$ )

$\Rightarrow$  *Recursive feasibility* ✓

$\Rightarrow J_0^*(x)$  is a *Lyapunov function*  $\rightarrow$  *(Lyapunov) Stability* ✓

## Stability of MPC - Zero terminal state constraint

Terminal constraint:  $x_N \in \mathcal{X}_f = 0$

- Assume feasibility of  $x_0$  and let  $\{u_0^*, u_1^*, \dots, u_{N-1}^*\}$  be the optimal control sequence computed at  $x_0$  and  $\{x(0), x_1, \dots, x_N\}$  be the corresponding state trajectory
- Apply  $u_0^*$  and let system evolve to  $x(1) = Ax_0 + Bu_0^*$
- At  $x(1)$  the control sequence  $\{u_1^*, u_2^*, \dots, u_{N-1}^*, 0\}$  is feasible (apply 0 control input  $\Rightarrow x_{N+1} = 0$ )

$\Rightarrow$  *Recursive feasibility* ✓

$\Rightarrow J_0^*(x)$  is a Lyapunov function  $\rightarrow$  (Lyapunov) Stability ✓

## Stability of MPC - Zero terminal state constraint

Terminal constraint:  $x_N \in \mathcal{X}_f = 0$

Goal: Show  $J_0^*(x_1) < J_0^*(x_0) \quad \forall x_0 \neq 0$

$$J_0^*(x_0) = \underbrace{p(x_N)}_{=0} + \sum_{i=0}^{N-1} q(x_i, u_i^*)$$

$$\begin{aligned} J_0^*(x_1) &\leq \tilde{J}_0(x_1) = \sum_{i=1}^N q(x_i, u_i^*) \\ &= \sum_{i=0}^{N-1} q(x_i, u_i^*) - q(x_0, u_0^*) + q(x_N, u_N) \\ &= J_0^*(x_0) - \underbrace{q(x_0, u_0^*)}_{\text{Subtract cost at stage 0}} + \underbrace{q(0, 0)}_{=0, \text{ Add cost for staying at 0}} \end{aligned}$$

$\Rightarrow J_0^*(x)$  is a Lyapunov function  $\rightarrow$  (Lyapunov) Stability ✓

## Example: Impact of Horizon with Zero Terminal Constraint

System dynamics:

$$x_{k+1} = \begin{bmatrix} 1.2 & 1 \\ 0 & 1 \end{bmatrix} x_k + \begin{bmatrix} 1 \\ 0.5 \end{bmatrix} u_k$$

Constraints:

$$\mathcal{X} := \{x \mid -50 \leq x_1 \leq 50, -10 \leq x_2 \leq 10\} = \{x \mid A_x x \leq b_x\}$$

$$\mathcal{U} := \{u \mid \|u\|_\infty \leq 1\} = \{u \mid A_u u \leq b_u\}$$

Stage cost:

$$q(x, u) := x' \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} x + u^T u$$

## Example: Impact of Horizon with Zero Terminal Constraint

The horizon can have a strong impact on the region of attraction.

# Table of Contents

## 6. Feasibility and Stability

### 6.1 Proof for $\mathcal{X}_f = 0$

### 6.2 General Terminal Sets

### 6.3 Example

## Extension to More General Terminal Sets

**Problem:** The terminal constraint  $x_N = 0$  reduces the size of the feasible set

**Goal:** Use convex set  $\mathcal{X}_f$  to increase the region of attraction

### Double integrator

$$x(t+1) = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(t)$$

$$\begin{bmatrix} -5 \\ -5 \end{bmatrix} \leq x(t) \leq \begin{bmatrix} 5 \\ 5 \end{bmatrix}$$

$$-0.5 \leq u(t) \leq 0.5$$

$$N = 5, Q = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, R = 10$$

**Goal:** Generalize proof to the constraint  $x_N \in \mathcal{X}_f$

## Invariant sets

### Definition: Invariant set

A set  $\mathcal{O}$  is called *positively invariant* for system  $x(t+1) = f_{cl}(x(t))$ , if

$$x(0) \in \mathcal{O} \Rightarrow x(t) \in \mathcal{O}, \quad \forall t \in \mathbb{N}_+$$

The positively invariant set that contains every closed positively invariant set is called the maximal positively invariant set  $\mathcal{O}_\infty$ .

## Stability of MPC - Main Result

### Assumptions

- 1 Stage cost is positive definite, i.e. it is strictly positive and only zero at the origin
- 2 Terminal set is **invariant** under the local control law  $v(x_k)$ :

$$x_{k+1} = Ax_k + Bv(x_k) \in \mathcal{X}_f, \quad \text{for all } x_k \in \mathcal{X}_f$$

All state and input **constraints are satisfied** in  $\mathcal{X}_f$ :

$$\mathcal{X}_f \subseteq \mathcal{X}, \quad v(x_k) \in \mathcal{U}, \quad \text{for all } x_k \in \mathcal{X}_f$$

- 3 Terminal cost is a continuous **Lyapunov function** in the terminal set  $\mathcal{X}_f$  and satisfies:

$$p(x_{k+1}) - p(x_k) \leq -q(x_k, v(x_k)), \quad \text{for all } x_k \in \mathcal{X}_f$$

Under those 3 assumptions:

### Theorem

The closed-loop system under the MPC control law  $u_0^*(x)$  is asymptotically stable and the set  $\mathcal{X}_f$  is positive invariant for the system  $x(k+1) = Ax + Bu_0^*(x)$ .

## Stability of MPC - Outline of the Proof

- Assume feasibility of  $x(0)$  and let  $\{u_0^*, u_1^*, \dots, u_{N-1}^*\}$  be the optimal control sequence computed at  $x(0)$  and  $\{x(0), x_1, \dots, x_N\}$  the corresponding state trajectory
- At  $x(1)$ ,  $\{u_1^*, u_2^*, \dots, v(x_N)\}$  is feasible:
  - $x_N$  is in  $\mathcal{X}_f \rightarrow v(x_N)$  is feasible
  - and  $x_{N+1} = Ax_N + Bv(x_N)$  in  $\mathcal{X}_f$

$\Rightarrow$  *Terminal constraint provides recursive feasibility*

## Stability of MPC - Outline of the Proof

- Assume feasibility of  $x(0)$  and let  $\{u_0^*, u_1^*, \dots, u_{N-1}^*\}$  be the optimal control sequence computed at  $x(0)$  and  $\{x(0), x_1, \dots, x_N\}$  the corresponding state trajectory
- At  $x(1)$ ,  $\{u_1^*, u_2^*, \dots, v(x_N)\}$  is feasible:  
 $x_N$  is in  $\mathcal{X}_f \rightarrow v(x_N)$  is feasible  
and  $x_{N+1} = Ax_N + Bv(x_N)$  in  $\mathcal{X}_f$

$\Rightarrow$  *Terminal constraint provides recursive feasibility*

## Asymptotic Stability of MPC - Outline of the Proof

$$J_0^*(x_0) = \sum_{i=0}^{N-1} q(x_i, u_i^*) + p(x_N)$$

Feasible, sub-optimal sequence for  $x_1$  :  $\{u_1^*, u_2^*, \dots, v(x_N)\}$

$$\begin{aligned}
 J_0^*(x_1) &\leq \sum_{i=1}^N q(x_i, u_i^*) + p(Ax_N + Bv(x_N)) \\
 &= \sum_{i=0}^{N-1} q(x_i, u_i^*) + p(x_N) - q(x_0, u_0^*) + p(Ax_N + Bv(x_N)) \\
 &\quad - p(x_N) + q(x_N, v(x_N)) \\
 &= J_0^*(x_0) - q(x_0, u_0^*) + \underbrace{p(Ax_N + Bv(x_N)) - p(x_N) + q(x_N, v(x_N))}_{p(x) \leq 0} \\
 &\Rightarrow J_0^*(x_1) - J_0^*(x_0) \leq -q(x_0, u_0^*), \quad q > 0
 \end{aligned}$$

$J_0^*(x)$  is a Lyapunov function decreasing along the closed loop trajectories

$\Rightarrow$  The closed-loop system under the MPC control law is asymptotically stable

## Choice of Terminal Sets and Cost - Linear System, Quadratic Cost

$$\begin{aligned}
 J_0^*(x_0) = \min_{U_0} \quad & \textcolor{red}{x_N}' P x_N + \sum_{k=0}^{N-1} x_k' Q x_k + u_k' R u_k \quad \textcolor{red}{\text{Terminal Cost}} \\
 \text{subj. to} \quad & x_{k+1} = A x_k + B u_k, \quad k = 0, \dots, N-1 \\
 & x_k \in \mathcal{X}, \quad u_k \in \mathcal{U}, \quad k = 0, \dots, N-1 \\
 & \textcolor{red}{x_N} \in \textcolor{red}{\mathcal{X}_f} \quad \textcolor{red}{\text{Terminal Constraint}} \\
 & x_0 = x(t)
 \end{aligned}$$

## Choice of Terminal Sets and Cost - Linear System, Quadratic Cost

- Design unconstrained LQR control law

$$F_\infty = -(B' P_\infty B + R)^{-1} B' P_\infty$$

where  $P_\infty$  is the solution to the discrete-time algebraic Riccati equation:

$$P_\infty = A' P_\infty A + Q - A' P_\infty B (B' P_\infty B + R)^{-1} B' P_\infty A$$

- Choose the terminal weight  $P = P_\infty$
- Choose the terminal set  $\mathcal{X}_f$  to be the maximum invariant set for the closed-loop system  $x_{k+1} = (A + B F_\infty) x_k$ :

$$x_{k+1} = A x_k + B F_\infty(x_k) \in \mathcal{X}_f, \quad \text{for all } x_k \in \mathcal{X}_f$$

All state and input **constraints are satisfied** in  $\mathcal{X}_f$ :

$$\mathcal{X}_f \subseteq \mathcal{X}, \quad F_\infty x_k \in \mathcal{U}, \quad \text{for all } x_k \in \mathcal{X}_f$$

## Choice of Terminal Sets and Cost - Linear System, Quadratic Cost

- 1 The stage cost is a positive definite function
- 2 By construction the terminal set is **invariant** under the local control law  $v = F_\infty x$
- 3 Terminal cost is a continuous **Lyapunov function** in the terminal set  $\mathcal{X}_f$  and satisfies:

$$\begin{aligned} x'_{k+1} P x_{k+1} - x'_k P x_k &= x'_k (-P_\infty + A' P_\infty A - A' P_\infty B (B' P_\infty B + R)^{-1} B' P_\infty A) x_k \\ &= -x'_k Q x_k \end{aligned}$$

All the Assumptions of the Feasibility and Stability Theorem are verified.

## Example: Unstable Linear System

System dynamics:

$$x_{k+1} = \begin{bmatrix} 1.2 & 1 \\ 0 & 1 \end{bmatrix} x_k + \begin{bmatrix} 1 \\ 0.5 \end{bmatrix} u_k$$

Constraints:

$$\mathcal{X} := \{x \mid -50 \leq x_1 \leq 50, -10 \leq x_2 \leq 10\} = \{x \mid A_x x \leq b_x\}$$

$$\mathcal{U} := \{u \mid \|u\|_\infty \leq 1\} = \{u \mid A_u u \leq b_u\}$$

Stage cost:

$$q(x, u) := x' \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} x + u^T u$$

Horizon:  $N = 10$

## Example: Designing MPC Problem

- 1 Compute the optimal LQR controller and cost matrices:  $F_\infty, P_\infty$
- 2 Compute the maximal invariant set  $\mathcal{X}_f$  for the closed-loop linear system  $x_{k+1} = (A + BF_\infty)x_k$  subject to the constraints

$$\mathcal{X}_{cl} := \left\{ x \mid \begin{bmatrix} A_x \\ A_u F_\infty \end{bmatrix} x \leq \begin{bmatrix} b_x \\ b_u \end{bmatrix} \right\}$$

## Example: Closed-loop behaviour

## Example: Closed-loop behaviour

## Example: Closed-loop behaviour

## Example: Closed-loop behaviour

## Example: Closed-loop behaviour

## Example: Lyapunov Decrease of Optimal Cost

## Stability of MPC - Remarks

- The terminal set  $\mathcal{X}_f$  and the terminal cost ensure recursive feasibility and stability of the closed-loop system.  
But: the terminal constraint reduces the region of attraction.  
(Can extend the horizon to a sufficiently large value to increase the region)

Are terminal sets used in practice?

- Generally not...
  - Not well understood by practitioners
  - Requires advanced tools to compute (polyhedral computation or LMI)
- Reduces region of attraction
  - A 'real' controller must provide *some* input in *every* circumstance
- Often unnecessary
  - Stable system, long horizon  $\rightarrow$  will be stable and feasible in a (large) neighbourhood of the origin

## Choice of Terminal Set and Cost: Summary

- Terminal constraint provides a sufficient condition for stability
- Region of attraction without terminal constraint may be larger than for MPC with terminal constraint but characterization of region of attraction extremely difficult
- $\mathcal{X}_f = 0$  simplest choice but small region of attraction for small  $N$
- Solution for linear systems with quadratic cost
- In practice: Enlarge horizon and check stability by sampling
- With larger horizon length  $N$ , region of attraction approaches maximum control invariant set

## Summary

**Finite-horizon MPC may not be stable!**

**Finite-horizon MPC may not satisfy constraints for all time!**

- An infinite-horizon provides stability and invariance.
- We ‘fake’ infinite-horizon by forcing the final state to be in an invariant set for which there exists an invariance-inducing controller, whose infinite-horizon cost can be expressed in closed-form.
- These ideas extend to non-linear systems, but the sets are difficult to compute.

## Table of Contents

6. Feasibility and Stability
  - 6.1 Proof for  $\mathcal{X}_f = 0$
  - 6.2 General Terminal Sets
  - 6.3 Example
7. Extension to Nonlinear MPC

## Extension to Nonlinear MPC

Consider the nonlinear system dynamics:  $x(t+1) = g(x(t), u(t))$

$$\begin{aligned}
 J_0^*(x(t)) = \min_{U_0} \quad & p(x_N) + \sum_{k=0}^{N-1} q(x_k, u_k) \\
 \text{subj. to} \quad & x_{k+1} = g(x_k, u_k), \quad k = 0, \dots, N-1 \\
 & x_k \in \mathcal{X}, \quad u_k \in \mathcal{U}, \quad k = 0, \dots, N-1 \\
 & x_N \in \mathcal{X}_f \\
 & x_0 = x(t)
 \end{aligned}$$

- Presented assumptions on the terminal set and cost did not rely on linearity
  - Lyapunov stability is a general framework to analyze stability of nonlinear dynamic systems
- Results can be directly extended to nonlinear systems.

However, computing the sets  $\mathcal{X}_f$  and function  $p$  can be very difficult!
